7 Solutions to the exercises 39

1 Introduction

Many commonly used crime datasets, including the NIBRS data we will encounter in the next set of notes, contain only crimes reported to the police. The National Crime Victimization Survey (NCVS) provides a different perspective by collecting self-reported victimization data. Each year, under the guidance of the Bureau of Justice Statistics, the U.S. Census Bureau interviews a sample of people 12 years old or older about the number and characteristics of crime victimizations they experienced during the prior 6 months.

In 2023, the NCVS completed 226,480 person interviews in 142,028 household interviews. The survey had a 63% response rate for households and an 82% response rate for individuals. Households remain in the sample for $3\frac{1}{2}$ years, completing interviews every 6 months, in person

or by phone, for a total of seven interviews. Current federal estimates put the annual cost at roughly $55M and the uncompensated respondent time at roughly 123,000 hours.

The NCVS contains information about nonfatal personal crimes, such as rape and robbery, as well as property crimes, such as burglary. Additional information about the NCVS can be found at the BJS website. To give a sense of the type of data that the NCVS contains, refer to the Official 2023 BJS Crime Victimization report.

2 Acquiring the NCVS data

The University of Michigan consolidates the NCVS data into a format that is easily accessible in R. We will be using data collected in 2022 and 2023 to assemble a dataset that covers victimizations occurring in 2022. Since respondents are asked about crime in the previous six months, respondents completing surveys in May 2023 will still be reporting about crimes in December 2022.

Why am I not using 2024 or 2025 data? In 2024, BJS used a split-sample design, giving half of the randomly selected households the legacy instrument and half the redesigned instrument. BJS has released the legacy data but has not released the data from the half that received the redesigned instrument. The survey fully transitioned to the redesigned instrument in 2025, but BJS has not announced a release date for those data. Data collection for crimes that occurred in 2025 will continue through June 2026. Data collected in 2026 will probably not be posted until fall 2027.

First, we will download the NCVS 2022 data, ICPSR 38603. Click on Download, select R, save the resulting file (called something like ICPSR_38603-V1.zip), extract the contents of the zipped file to a convenient folder, and give it a more understandable folder name, like NCVS2022. Repeat the process for downloading the NCVS 2023 data, ICPSR 38962. New NCVS data tends to appear in mid-September. Typically we need to wait about nine months to get the results from the previous year.

After unzipping the NCVS files, you will find subfolders called DS0001, DS0002, DS0003, DS0004, and DS0005.

```

Inside each of these subfolders you will see an R data file with the extension .rda. We will spend most of our attention on the contents of the DS0005 folder, which contains the "incident-level extract file." In each folder you will also find codebooks in PDF (and EPUB) format. The codebook is as important as it is tedious for understanding what is stored in the NCVS data. You should become familiar with the codebooks as soon as you can.

Let's start loading these datasets. We will skip the DS0001 subfolder, which contains basic survey information on the targeted addresses. The DS0002 folder contains data on the households included in the survey.

```
load("NCVS2022/DS0002/38603-0002-Data.rda")
load("NCVS2023/DS0002/38962-0002-Data.rda")

# and let's give them nicer names
dataHH22 <- da38603.0002
dataHH23 <- da38962.0002
```

Take a peek at the first couple of rows.

```
library(dplyr)
library(tidyr)

dataHH22 |>

```

The 2022 household dataset has 448 columns. Instead of printing out all of them, I just picked out 17 columns here. First off, you can see that the column names are generally not helpful. That is where the codebook comes in handy. The codebook tells you what each variable means.

Somewhat hidden is a table linking column names to English explanations of what is in those columns. You can get to it by extracting the data frame's "attributes" with `attr()`.

```
varsHH <- dataHH22 |>
   attr("variable.labels") |>
   data.frame() |>
   tibble::rownames_to_column() |>
   setNames(c("varname","details")) |>
   filter(!grepl("^HHREP", varname)) # exclude rows that start with HHREP
```

Now `varsHH` has two columns, the first with the column names and the second with the details. Let's pull up the 17 columns listed before.

```
varsHH |>
   filter(varname %in% c("V2001","YEARQ","IDHH","V2003","V2014","V2016",
                         "V2018","V2020","V2030","V2031","V2032","V2034","V2036",
                         "V2038","V2040A","V2127B","V2129"))
```

```
   varname                                                 details
1    V2001                                    HOUSEHOLD RECORD TYPE
2    YEARQ                  YEAR AND QUARTER OF INTERVIEW (YYYY.Q)
3     IDHH                                  NCVS ID FOR HOUSEHOLDS
```

```
4    V2003                   YEAR AND QUARTER IDENTIFICATION NUMBER
5    V2014                                        TENURE (ORIGINAL)

9    V2030                                 REASON FOR NONINTERVIEW
10   V2031                    RACE OF HH HEAD (TYPE A NONINTERVIEW)
11   V2032                  PRINCIPAL PERSON RELATION TO REF PERSON
12   V2034                   PRINCIPAL PERSON MARITAL STATUS (CURR)
13   V2036                         PRINCIPAL PERSON SEX (ALLOCATED)
14   V2038                  PRINCIPAL PERSON EDUCATIONAL ATTAINMENT
15  V2040A            PRINCIPAL PERSON RACE RECODE (START 2003 Q1)
16  V2127B REGION - 1990, 2000, 2010 SAMPLE DESIGN (START 1995 Q3)
17   V2129                                              MSA STATUS
```

These are much more intelligible descriptions. "SMSA" stands for Standard Metropolitan Statistical Area, an outdated term. Today we simply call them MSAs. Under the current federal standards, an MSA must contain an urban area with at least 50,000 people.

Note the first household record has `IDHH` equal to 180900025854368056823612 5. We can load the respondent "person file" to see who in this household responded.

```r
# loading person-level data
load("NCVS2022/DS0003/38603-0003-Data.rda")
load("NCVS2023/DS0003/38962-0003-Data.rda")
dataPers22 <- da38603.0003
dataPers23 <- da38962.0003

# lookup respondents from this household
dataPers22 |>
  filter(IDHH=="180900025854368056823612 5") |>
  select(!starts_with("PERREP"))  # drop all the PERREP weight columns
```

```
              V3001  YEARQ                       IDHH

```

These rows represent two surveys occurring at the same time. One is of the reference person, a married white female, and the second is of her husband.

Let's grab the variable details as we did with the household data.

```
# Person file also has list of variable details
varsPers <- dataPers22 |>
   attr("variable.labels") |>
   data.frame() |>
   tibble::rownames_to_column() |>
   setNames(c("varname","details")) |>
   filter(!grepl("^(PERREP|PINTTYPE)", varname))
varsPers

5  (58) Theft value NA
6 (20) Verbal thr aslt
```

Finally, we will load in the incident extract file and its associated variable details. This extract file merges in household-level and person-level information to the incident-level file, allowing you to connect person-level features with features of the victimizations they report.

```
# incident-level extract file
load("NCVS2022/DS0005/38603-0005-Data.rda")
load("NCVS2023/DS0005/38962-0005-Data.rda")
dataExt22 <- da38603.0005
dataExt23 <- da38962.0005

varsExt <- dataExt22 |>
   attr("variable.labels") |>
   data.frame() |>
   tibble::rownames_to_column() |>
   setNames(c("varname","details")) |>
   filter(!grepl("INCREPWGT|VICREPWGT", varname))
```

Let's take a look at a few of the reported crime victimizations. Here, I will just pull the respondent's age, marital status, sex, general location, and crime type.

```
dataExt22 |>
  select(V3014, V3015, V3018, V4022, V4529) |>
  slice(1:3)
```

```
  V3014        V3015      V3018             V4022                V4529
1    56 (3) Divorced (2) Female (3) Same city etc (31) Burg, force ent
2    78  (2) Widowed (2) Female (3) Same city etc  (56) Theft $50-$249
3    43  (1) Married   (1) Male (3) Same city etc  (56) Theft $50-$249
```

Not all information from the household and person files is in the extract file, but many of the features that are likely to be of interest are there.

Now that the datasets are loaded and renamed, we can remove objects from our working environment that we no longer need. We can use `rm()` to accomplish this.

```
rm(da38603.0002,da38603.0003,da38603.0004,da38603.0005,
   da38962.0002,da38962.0003,da38962.0004,da38962.0005)
```

3 Combining 2022 and 2023 data

Here we are going to create a data frame containing all the reported incidents that *occurred* in 2022. Take a look at the month and year of the reported crime incidents.

```
dataExt22 |> count(V4015, V4014)
```

```
   V4015          V4014   n
1   2021      (07) July 138
2   2021    (08) August 280
3   2021 (09) September 384
4   2021   (10) October 510
5   2021  (11) November 650
6   2021  (12) December 849
7   2022   (01) January 772
8   2022  (02) February 727
9   2022     (03) March 774
10  2022     (04) April 730
11  2022       (05) May 770
12  2022      (06) June 839
13  2022      (07) July 718
14  2022    (08) August 593
15  2022 (09) September 383
16  2022   (10) October 292
17  2022  (11) November 136
```

```
dataExt23 |> count(V4015, V4014)
```

```
   V4015          V4014   n
1   2022      (07) July 175
2   2022    (08) August 253
```

```
3   2022 (09) September 364
4   2022   (10) October 524
5   2022  (11) November 674
6   2022  (12) December 859
7   2023   (01) January 753
8   2023  (02) February 681
9   2023     (03) March 699
10  2023     (04) April 688
11  2023       (05) May 738
12  2023      (06) June 760
13  2023      (07) July 721
14  2023    (08) August 573
15  2023 (09) September 447
16  2023   (10) October 273
17  2023  (11) November 142
```

Note that the 2022 NCVS reports on crimes that occurred in 2022 and 2021. Similarly, the 2023 NCVS reports on crimes that occurred in 2023 and 2022. Remember that the NCVS surveys respondents about victimizations from the prior 6 months, excluding the month of the interview. We are going to stack the 2022 and 2023 incident extract data frames and then filter them to exclude 2021 and 2023.

`bind_rows()` stacks data frames on top of each other, useful when combining two datasets that have the same structure. First we will check that they have the same columns in them.

```
identical(names(dataExt22), names(dataExt23))
```

```
[1] TRUE
```

Good so far! Now let's try to stack them.

```
dataExt <- dataExt22 |>
  bind_rows(dataExt23)
```

```
Error in `bind_rows()`:
! Can't combine `..1$V2061` <factor<f6015>> and `..2$V2061` <double>.
```

Hmmm… R is complaining about `V2061`. Note that it specifically complains that one data frame has `V2061` stored as a factor (a categorical variable) and the other one has it stored as a double, a decimal number.

```
dataExt22 |> count(V2061)
```

```
   V2061    n
1 (01) 1    8
2   <NA> 9537
```

```
dataExt23 |> count(V2061)
```

```
  V2061    n
1     1   14
2     3    1
3     4    3
4    NA 9306
```

What is `V2061` anyway?

```
varsExt |> filter(varname=="V2061")
```

```
  varname                           details
1   V2061 LINE NO. OF 4TH PROXY RESPONDENT
```

This reports on who answered on behalf of an unavailable respondent. It is not really important for us, so let's drop this one by using `select(-V2061)` on both data frames.

```
dataExt <- dataExt22 |>
  select(-V2061) |>
  bind_rows(dataExt23 |>
              select(-V2061))
```

```
Error in `bind_rows()`:
! Can't combine `..1$V4126` <factor<fb04b>> and `..2$V4126` <double>.
```

Ughh. Now it is complaining about `V4126`.

```
varsExt |> filter(varname=="V4126")
```

```
  varname                                 details
1   V4126 WHICH INJURY FROM OTHER WEAPON (3RD)
```

```
dataExt22 |> count(V4126)
```

```
               V4126    n
1 (10) Bruises, cuts    3
2               <NA> 9542
```

```
dataExt23 |> count(V4126)
```

```
  V4126    n
1    NA 9324
```

In the codebook we can find the full question: "Q.33.3 Which injuries were caused by a weapon OTHER than a gun or knife?". This seems like a potentially interesting question that I probably do not want to discard. The issue is that no 2023 respondent said there was a third weapon that injured them. In 2022 `V4126` was stored as a factor, but in 2023, since they are all missing, R defaulted to numeric (double). We can fix this by just telling R to convert the 2023 data into a factor.

```
dataExt <- dataExt22 |>
  select(-V2061) |>
  bind_rows(dataExt23 |>
              select(-V2061) |>
              mutate(V4126=as.factor(V4126)))
```

```
Error in `bind_rows()`:
! Can't combine `..1$V4313` <factor<514cc>> and `..2$V4313` <double>.
```

Dammit! Now it is complaining about `V4313`. What is the problem with this one? Again we have a problem with 2022 storing as a factor and 2023 storing as a double.

```
varsExt |> filter(varname=="V4313")
```

```
  varname                                  details
1   V4313 3RD LINE NO. OF OTHER OWNER THEFT ITEMS
```

```
dataExt22 |> count(V4313)
```

```
   V4313    n
1 (06) 6    2
2   <NA> 9543
```

```
dataExt23 |> count(V4313)
```

```
  V4313    n
1     4    1
2     5    1
3    NA 9322
```

This column answers "Besides the respondent, which household member(s) owned the (property/money) the offender tried to take?" In 2022, the only responses were missing or #6. In 2023, the responses were missing, 4, or 5. These should be numbers since they are supposed to link to respondents in the same household affected by the theft. The approach I'll take is to use `recode_values()`, telling R to change the 2022 "(06) 6" response to a regular 6.

```
dataExt <- dataExt22 |>
  select(-V2061) |>
  mutate(V4313 = recode_values(V4313,
                               "(06) 6" ~ 6,
                               default = NA)) |>

  bind_rows(dataExt23 |>
              select(-V2061) |>
              mutate(V4126=as.factor(V4126)))
```

```
Error in `bind_rows()`:
! Can't combine `..1$V4357A` <double> and `..2$V4357A` <factor<758b7>>.
```

Will this ever stop?!?!? Another double in one year and factor in another year, this time affecting `V4357A` asking about handguns.

```
varsExt |> filter(varname=="V4357A")
```

```
  varname                                          details
1  V4357A HOW MANY HANDGUNS WERE TAKEN (START 2004 Q1)
```

```
dataExt22 |> count(V4357A)
```

```
  V4357A    n
1      1   41
2      2    8
```

```
3      3    3
4    997    1
5    998    1
6     NA 9491
```

```
dataExt23 |> count(V4357A)
```

```
         V4357A    n
1       (001) 1   48
2 (998) Residue    1
3          <NA> 9275
```

You might have seen this word "Residue" show up before. For the NCVS, BJS records "Residue" when there is a data entry error resulting in an out-of-range code, an incorrect or unusable answer by the respondent, or the absence of an entry for a question that should have been asked. Sometimes you might also see "Out of universe/blank." This happens when a question is outside the set that a respondent should answer. For example, only victims who report being injured are asked whether they received medical care. All other victims skip the question.

I will solve this issue by recoding the 2023 values to numeric values.

```
dataExt <- dataExt22 |>
  select(-V2061) |>
  mutate(V4313 = recode_values(V4313,
                               "(06) 6" ~ 6,
                               default = NA)) |>
  bind_rows(dataExt23 |>
              select(-V2061) |>
              mutate(V4126 = as.factor(V4126),
                     V4357A = recode_values(V4357A,
                                            "(001) 1" ~ 1,
                                            "(998) Residue" ~ 998,
                                            default=NA)))
```

Success! Now let's check that all is okay now.

```
dataExt |> count(V4126)
```

```
               V4126     n
1 (10) Bruises, cuts     3
2               <NA> 18866
```

```
dataExt |> count(V4313)
```

```
  V4313     n
1     4     1
2     5     1
3     6     2
4    NA 18865
```

```
dataExt |> count(V4357A)
```

```
  V4357A     n
1      1    89
2      2     8
3      3     3
4    997     1
5    998     2
6     NA 18766
```

Remember that we still have data in here from 2021 and 2023.

```
table(dataExt$V4015)
```

```
2021 2022 2023
2811 9583 6475
```

We are just going to focus on 2022.

```
dataExt <- dataExt |> filter(V4015==2022)
```

Note that BJS official reports generally classify victimizations by the year of the survey and not by the year of the crime. Our 2022 calendar-year dataset combines records carrying collection-year weights from two survey years, so its estimates will not exactly reproduce the official 2022 estimates.

Some respondents report crime victimizations that occurred outside of the United States.

```
# V4022 - IN WHAT CITY, TOWN, VILLAGE.
dataExt |> count(V4022)
```

```
                V4022    n
1    (1) Outside U.S.   44
2 (2) Not in city etc   67
3   (3) Same city etc 8069
4   (4) Diff city etc 1354
5      (5) Don't know   37
6         (8) Residue   12
```

The BJS convention is to exclude these crimes in official reports (see 2023 User Guide, page 21).

```
dataExt <- dataExt |>
  filter(is.na(V4022) | V4022!="(1) Outside U.S.")
```

There is also an important labeling error in `V4021B`, the time of day when the victimization occurred. Here is the variable as it appears in the extract file.

```
table(dataExt$V4021B)
```

```
    (01) Aft 6am-12am     (02) Aft 12am-3pm      (03) Aft 3pm-6pm
                  948                  1310                  1037
  (04) DK time of day      (05) Aft 6pm-9pm     (06) Aft 9pm-12pm
                  878                   804                   696
    (07) Aft 12pm-6am (08) DK time of night     (09) DK day/night
                 1783                   799                  1263
         (98) Residue
                   21
```

The original questionnaire uses the unambiguous terms "12 noon" and "12 midnight" (Figure 1). The extract file instead labels noon as 12 a.m. and midnight as 12 p.m. The numeric response codes are correct. Only the four factor labels that meet at noon or midnight are wrong.

We can repair the labels with `replace_values()`. Code 2 begins after noon and code 7 begins after midnight, while codes 1 and 6 end at those same boundaries. Since `V4021B` is a factor and the corrected labels are new factor levels, we first convert it to character and then convert the result back to a factor.

```
dataExt <- dataExt |>
  mutate(V4021B = V4021B |>
    as.character() |>
    replace_values(
```

```

4 Sampling weights

A sampling weight tells us how many units in the population a sampled record represents. The NCVS interviews a sample of U.S. households and people, so one record in the data may

represent hundreds or thousands of victimizations in the population. To estimate a national total, we sum the weights rather than count the rows. To estimate a percentage, we sum the weights for records with the feature of interest and divide by the sum of all the relevant weights. The weights account for the sample design, adjust for nonresponse, and calibrate the sample to known population totals.

The NCVS sampling design has historically emphasized stability and operational continuity, relying heavily on Census Bureau sampling and fieldwork logistics. A 2008 National Academies report noted that the original design gave each household the same probability of selection, even though such a design was not optimal for many uses of the NCVS, and recommended giving housing units higher selection probabilities where victimization rates were higher. At the first stage, the design has generally sampled counties with probabilities approximately proportional to population size, without including a local crime-rate measure. Research suggests that police-reported crime rates and tract-level demographic measures can predict victimization and could improve precision, but those measures are not currently part of the sampling plan. The sampling weights are still essential because selection probabilities vary for other design reasons, and the weights also adjust for nonresponse and calibrate the sample to known population totals.

Constructing the sampling weights is a complex process (see the User Guide "Weights Details" section starting on page 22). The NCVS sampling weights adjust for six factors. From the User Guide:

1. *Base weight*: The inverse of the national sampling rate for the stratum of that unit (person or household)
2. *Weighting control*: Adjusts for any subsampling due to unexpected events in the field, such as new construction, area segments larger than anticipated, and other deviations from the overall stratum sampling rate
3. *Household noninterview adjustment*: Adjusts for nonresponse at the household level by increasing the weights of interviewed households most similar to households not interviewed in terms of race, MSA status of residence, and urban/suburban/rural status of residence. This inflates the weight assigned to interviewed households so that they represent themselves and noninterviewed households. The noninterviewed cases are assigned a weight of zero, excluding them from population estimates
4. *Within-household noninterview adjustment*: Adjusts for nonresponse at the person level by increasing the weights of interviewed persons most similar to persons not interviewed in terms of region, age, race, sex, and household composition. The adjustment inflates the weight assigned to completed interviews so that they represent themselves and sampled individuals who were not interviewed. The noninterviewed cases are assigned a weight of zero
5. *First-stage ratio estimate factor*: Adjusts for differences between the characteristics of sampled non-self-representing (NSR) primary sampling units (PSUs) and independent

measures of the population in NSR PSUs. For self-representing PSUs, this factor is set to 1. The factor adjusts for PSU differences in region, MSA status, urban/suburban/rural status, and racial composition. (PSUs are essentially counties… or a small group of counties.)

6. *Second-stage ratio estimate factor*: A poststratification factor defined for each person to adjust for the difference between weighted counts of persons, using the five weight components above, and independent estimates of the number of persons within certain age-by-race-by-sex categories. These independent estimates are based on Census population controls adjusted for the undercount

> **Always use the sampling weights**
>
> Importantly, every population estimate you produce with the NCVS must use the appropriate weights. Use `SERIES_WEIGHT` for victimization totals and percentages, and use `SERIES_IWEIGHT` when the unit of interest is a criminal incident. To estimate a victimization rate, divide the weighted number of victimizations by the weighted population at risk. Use person weights for personal crimes (`WGTPERCY`) and household weights (`WGTHHCY`) for household property crimes. Even plots and figures intended to describe the U.S. population should use weights. Unweighted tabulations are still useful for checking the data, but they should not be presented as national estimates.

Where you would normally compute a sample mean as $\frac{\sum x_i}{n}$, the weighted mean is

$$\frac{\sum w_i x_i}{\sum w_i}$$

For a weighted percentage, total all the weights for records with the particular feature and divide by the total weight. For some plots there is not an obvious way to accommodate the sampling weights. In those cases, we can sample with replacement with probabilities proportional to the sampling weights and plot the sampled points.

This chapter focuses on point estimates. To calculate valid standard errors and confidence intervals, you also need to account for the complex sample design. The incident extract includes 160 replicate weights for this purpose, and BJS uses balanced repeated replication with Fay's method.

For estimating victimization totals in the incident extract, we will focus on two weights. `WGTVICCY` is the adjusted collection-year victimization weight. It tells us how many victimizations a record represents when that record is counted once. `SERIES_WEIGHT` begins with `WGTVICCY` and also accounts for series crimes.

Some crimes happen in a series. For example, a respondent may report regular domestic abuse that happened numerous times over the last six months. Each occurrence of domestic abuse is a victimization, but the BJS convention is to count up to 10 occurrences for crimes reported as

a series (2023 User Guide, pages 18-19). For a nonseries crime, `SERIES_WEIGHT` and `WGTVICCY` are equal. For a series crime, `SERIES_WEIGHT` is `WGTVICCY` multiplied by the reported number of occurrences, capped at 10. If the number of occurrences is unavailable, BJS uses six.

Variable `V4016` records the answer to "Altogether, how many times did this type of incident happen during the last 6 months?" and variable `V4019` documents "Can you (respondent) recall enough details of each incident to distinguish them from each other?" Note that the coding of `V4016` has 997 representing "Don't know" and 998 representing "Residue." These are not counts of victimizations. Fortunately, `SERIES_WEIGHT` already incorporates the series adjustment, so we do not need to change `V4016` ourselves.

The ratio of `SERIES_WEIGHT` to `WGTVICCY` shows how many victimizations each record contributes after the series adjustment. The ratio is 1 for nonseries crimes and ranges from 2 to 10 for the series crimes shown below.

```
dataExt |>
  mutate(seriesMultiplier = SERIES_WEIGHT/WGTVICCY) |>
  filter(seriesMultiplier > 1) |>
  select(V4016, V4019, WGTVICCY, SERIES_WEIGHT, seriesMultiplier) |>
  head()
```

```
  V4016              V4019  WGTVICCY SERIES_WEIGHT seriesMultiplier
1     7 (2) No (is series) 2315.6980     16209.886                7
2     6 (2) No (is series)  418.0296      2508.178                6
3     6 (2) No (is series) 1899.7567     11398.540                6
4     6 (2) No (is series) 2235.6122     13413.673                6
5     7 (2) No (is series) 1560.4005     10922.804                7
6    30 (2) No (is series) 3059.0421     30590.421               10
```

> **Exercises**
>
> 1. Compare `nrow(dataExt)`, `sum(dataExt$WGTVICCY)`, and `sum(dataExt$SERIES_WEIGHT)`. What does each number represent?
> 2. Calculate the percentage increase from `WGTVICCY` to `SERIES_WEIGHT`. This is the effect of accounting for series victimizations on the estimated total.

5 Tabulating victimizations

First, we need to be clear about what we are counting. BJS reports on *victimizations* and *incidents*. For personal crimes, victimizations count the number of people victimized. For

household property crimes, the affected household is treated as the victim. Incidents count criminal events, and a single incident can involve multiple victims. BJS reports largely focus on criminal victimizations.

We can start by just asking the NCVS data how many criminal victimizations there were in 2022. We compute that as the sum of all the weights.

```
sum(dataExt$SERIES_WEIGHT)
```

```
[1] 20121320
```

This means that the NCVS estimates that there were 20,121,320 criminal victimizations in the United States in 2022.

Let's take a closer look at what kinds of victimization occurred. Note that this code breaks the dataset into groups based on the reported crime type, `V4529`, and computes the total weight associated with each of those crime categories.

```
dataExt |>
  group_by(V4529) |> # crime type
  summarize(total = sum(SERIES_WEIGHT)) |>
  print(n=Inf)
```

```
# A tibble: 33 x 2
   V4529                        total
   <fct>                        <dbl>
 1 (01) Completed rape        127522.
 2 (02) Attempted rape         67330.
 3 (03) Sex aslt w s aslt      27038.
 4 (04) Sex aslt w m aslt       7511.
 5 (05) Rob w inj s aslt       87026.
 6 (06) Rob w inj m aslt       88620.
 7 (07) Rob wo injury         216589.
 8 (08) At rob inj s asl       25197.
 9 (09) At rob inj m asl       47896.
10 (10) At rob w aslt         119279.
11 (11) Ag aslt w injury      449842.
12 (12) At ag aslt w wea      397249.
13 (13) Thr aslt w weap       637952.
14 (14) Simp aslt w inj       578068.
15 (15) Sex aslt wo inj       118078.
16 (16) Unw sex wo force       52425.
```

```
17 (17) Asl wo weap, wo inj 1295757.
18 (18) Verbal thr rape       41862.
19 (19) Ver thr sex aslt      15501.
20 (20) Verbal thr aslt     1978623.
21 (21) Purse snatching       35375.
22 (23) Pocket picking       124503.
23 (31) Burg, force ent      549203.
24 (32) Burg, ent wo for    1074214.
25 (33) Att force entry      312530.
26 (40) Motor veh theft      518797.
27 (41) At mtr veh theft     193058.
28 (54) Theft < $10          623035.
29 (55) Theft $10-$49       1735619.
30 (56) Theft $50-$249      2968819.
31 (57) Theft $250+         3057945.
32 (58) Theft value NA      1799273.
33 (59) Attempted theft      749585.
```

The first 20 crime types listed are violent crimes, codes 21 through 23 are personal larceny (like pickpocketing… no violence or breaking into a home), and the remainder are household property crimes. For household property crimes, the NCVS treats the household, rather than an individual respondent, as the victim. Let's extract the two-digit code between the parentheses so that we can classify the crime types.

```
dataExt <- dataExt |>
   mutate(crimeCode = as.integer(gsub("^\\(([0-9]{2})\\).*", "\\1", V4529)),
          crimeType = case_when(
             crimeCode <= 20 ~ "violent",
             crimeCode <= 23 ~ "personal larceny",
             .default = "property"))

dataExt |>
   select(V4529, crimeCode, crimeType) |>
   head()
```

```
                  V4529 crimeCode crimeType
1 (41) At mtr veh theft        41  property
2  (59) Attempted theft        59  property
3   (58) Theft value NA        58  property
4      (57) Theft $250+        57  property
5    (55) Theft $10-$49        55  property
6    (07) Rob wo injury         7   violent
```

That all looks correct, so now I can move on to the tabulation.

```
a <- dataExt |>
   group_by(crimeType) |>
   summarize(estTotal = sum(SERIES_WEIGHT))
a
```

```
# A tibble: 3 x 2
  crimeType         estTotal
  <chr>                <dbl>
1 personal larceny   159878.
2 property         13582078.
3 violent           6379364.
```

In our calendar-year 2022 dataset, there were an estimated 6,379,364 violent victimizations, 159,878 personal larcenies, and 13,582,078 household property victimizations.

We can summarize other categories, like car thefts, attempted and completed.

```
dataExt |>
  filter(V4529 %in% c("(40) Motor veh theft",
                      "(41) At mtr veh theft")) |>
  summarize(sum(SERIES_WEIGHT))
```

```
  sum(SERIES_WEIGHT)
1           711855.4
```

Measuring sexual assault has been complicated by numerous, sometimes major, changes (improvements, more precisely) in the definitions and data collection methods (e.g., question wording). The FBI's Uniform Crime Reporting Program made a major change to the definition of rape in 2013. The NCVS began phasing in its most recent instrument change in 2024. See Fisher and Gross (2025) for an extended discussion and timeline of the changes.

Here is the NCVS estimate of the number of rapes (attempted and completed) for 2022.

```
dataExt |>
  filter(V4529 %in% c("(01) Completed rape",
                      "(02) Attempted rape")) |>
  summarize(sum(SERIES_WEIGHT))
```

```
  sum(SERIES_WEIGHT)
1           194852.7
```

Official NCVS reports combine rape and sexual assault. There are a lot of crime categories that describe these victimizations.

```

Let's count any that have the word "rape" and any that have the word "sex" (sometimes capitalized). Here are the ones that BJS counts in this category.

```
dataExt |>
  filter(grepl("rape|[Ss]ex", V4529)) |>
  distinct(V4529)
```

```
                  V4529
1  (19) Ver thr sex aslt
2 (04) Sex aslt w m aslt
3 (03) Sex aslt w s aslt
4  (16) Unw sex wo force
5    (02) Attempted rape
6   (15) Sex aslt wo inj
7   (18) Verbal thr rape
8    (01) Completed rape
```

The estimated number of all sexual assaults in 2022 in the United States is

```
dataExt |>
  filter(grepl("rape|[Ss]ex", V4529)) |>
  summarize(sum(SERIES_WEIGHT))
```

```
  sum(SERIES_WEIGHT)
1             457268
```

Since 2020, we have not had national police-reported crime estimates. The FBI transitioned away from the traditional Summary Reporting System (SRS) series in 2021, and its replacement, NIBRS, has had low participation rates with minimal reporting from California, New York, Florida, and Pennsylvania.

The NCVS's value lies in its inclusion of victimizations that were never reported to police.

> **i** Exercises
>
> 3. Using `crimeType`, calculate the weighted percentage of all victimizations in each of the three categories: violent crime, personal larceny, and household property crime
> 4. Estimate the number and weighted percentage of motor vehicle thefts that were attempts rather than completed thefts

6 Calculating victimization by demographics

In the remainder of these notes, we will examine relationships between personal victimization and respondents' features, like age (`V3014`), marital status (`V3015`), and sex (`V3018`). To make the code clearer, let's give these variables more intelligible names.

```
dataExt <- dataExt |>
  rename(age=V3014, marital=V3015, sex=V3018)
```

Perhaps we are interested in which personal crimes disproportionately affect men and which disproportionately affect women. Household property crimes are attributed to the household rather than to an individual victim, so we will exclude them from these demographic comparisons. Start by tabulating personal crime type by sex.

```
dataExt |>
  filter(crimeCode <= 23) |>
  group_by(V4529, sex) |>
  summarize(count=sum(SERIES_WEIGHT)) |>
   print(n=Inf)
```

```

R produces a long narrow table. This format is sometimes useful, particularly when merging data frames. However, in this case having a table with counts for men and women side-by-side would be easier to absorb. `pivot_wider()` will swing the sex column into two side-by-side columns.

```
dataExt |>
  filter(crimeCode <= 23) |>
  group_by(V4529, sex) |>
  summarize(count=sum(SERIES_WEIGHT)) |>
  pivot_wider(names_from=sex,
              values_from=count,
              values_fill = 0) |> # fill in NAs with 0
  print(n=Inf)
```

```

Sexual assaults disproportionately affect women, while pocket picking and attempted robbery involving assaults disproportionately affect men.

The sequence `group_by()`, `summarize()`, `ungroup()` is so common that there is an alternative way to do the same calculation more compactly with `.by` in `summarize()`. A frequent R error is to use `group_by()`, then forget that the data is still grouped, and continue to do calculations unaware that they are occurring only within groups. The `.by` argument also helps avoid this error.

```
# can reduce the group_by, summarize, ungroup with .by
dataExt |>
  filter(crimeCode <= 23) |>
  summarize(count=sum(SERIES_WEIGHT),
            .by = c(V4529, sex)) |> # eliminates group/ungroup
  pivot_wider(names_from  = sex,
              values_from = count,
              values_fill = 0) |>
```

```
  rename(male=`(1) Male`, female=`(2) Female`) |>

Exercise

5. Repeat the demographic analysis using marital status. For each marital-status group, calculate the weighted percentage of personal victimizations in every crime category. Which crime types make up a larger percentage among divorced respondents than among married respondents?

Since we have made many changes to the dataset, I find it useful to save the final version. This way I can simply `load()` the data again later and know that it already has all the edits and changes that I have made.

```
save(dataExt, file="NCVS2022.RData", compress=TRUE)
```

7 Solutions to the exercises

1. Compare `nrow(dataExt)`, `sum(dataExt$WGTVICCY)`, and `sum(dataExt$SERIES_WEIGHT)`. What does each number represent?

```
nrow(dataExt)
```

```
[1] 9539
```

```
sum(dataExt$WGTVICCY)
```

```
[1] 18201324
```

```
sum(dataExt$SERIES_WEIGHT)
```

```
[1] 20121320
```

`nrow(dataExt)` is the unweighted number of records in our extract. `sum(dataExt$WGTVICCY)` is the estimated number of victimizations when every series record is counted once. `sum(dataExt$SERIES_WEIGHT)` is the estimated number of victimizations after counting up to 10 occurrences of each series crime.

2. Calculate the percentage increase from `WGTVICCY` to `SERIES_WEIGHT`. This is the effect of accounting for series victimizations on the estimated total.

```
100*(sum(dataExt$SERIES_WEIGHT)/sum(dataExt$WGTVICCY)-1)
```

```
[1] 10.54866
```

3. Using `crimeType`, calculate the weighted percentage of all victimizations in each of the three categories: violent crime, personal larceny, and household property crime

```
dataExt |>
   summarize(count=sum(SERIES_WEIGHT), .by=crimeType) |>
   mutate(percent=100*count/sum(count))
```

```
         crimeType      count    percent
1         property 13582077.9 67.5009293
2          violent  6379364.0 31.7045010
3 personal larceny   159877.9  0.7945696
```

4. Estimate the number and weighted percentage of motor vehicle thefts that were attempts rather than completed thefts

```
dataExt |>
  filter(V4529 %in% c("(40) Motor veh theft",
                      "(41) At mtr veh theft")) |>
  summarize(count=sum(SERIES_WEIGHT), .by=V4529) |>
  mutate(percent=100*count/sum(count))
```

```
                 V4529    count  percent
1 (41) At mtr veh theft 193058.2 27.12043
2  (40) Motor veh theft 518797.1 72.87957
```

5. Repeat the demographic analysis using marital status. For each marital-status group, calculate the weighted percentage of personal victimizations in every crime category. Which crime types make up a larger percentage among divorced respondents than among married respondents?

```
dataExt |>
   filter(crimeCode <= 23,
          marital %in% c("(1) Married",
                         "(2) Widowed",
                         "(3) Divorced",
                         "(4) Separated",
                         "(5) Never married")) |>
```

```r
  summarize(count=sum(SERIES_WEIGHT),
            .by=c(V4529, marital)) |>
  pivot_wider(names_from=marital,
              values_from=count,
              values_fill=0) |>
  mutate(across(-V4529, function(x) 100*x/sum(x)),
         difference=`(3) Divorced`-`(1) Married`) |>
  arrange(desc(difference)) |>
  print(n=Inf)
```

```
